STABILITY OF THE EXIT TIME FOR LÉVY PROCESSES

PHILIP S. GRIFFIN,* Syracuse University

ROSS A. MALLER,** Australian National University

Abstract
This paper is concerned with the behaviour of a Lévy process when it crosses over a positive level, \( u \), starting from 0, both as \( u \) becomes large and as \( u \) becomes small. Our main focus is on the time, \( \tau_u \), it takes the process to transit above the level, and in particular, on the stability of this passage time; thus, essentially, whether or not \( \tau_u \) behaves linearly as \( u \downarrow 0 \) or \( u \to \infty \). We also consider conditional stability of \( \tau_u \) when the process drifts to \(-\infty\), a.s.
This provides information relevant to quantities associated with the ruin of an insurance risk process, which we analyse under a Cramér condition.

Keywords: Lévy process; passage time above a level; stability; insurance risk process; Cramér condition; overshoot.

1. Introduction

For a random walk \( S \) starting from 0 with a positive step length distribution and having finite mean, the number of steps required to first pass a positive level \( u \), \( \tau_u^S \), say, is, for large \( u \), asymptotic to a multiple of \( u \), the constant of proportionality being the reciprocal of the mean step length. More precisely, \( \tau_u^S / u \to 1/c \)

as \( u \to \infty \), and, further, \( E\tau_u^S/u \to 1/c \) as \( u \to \infty \), where \( c \in (0, \infty) \) is the expected step length. These express a kind of long term linearity of the passage time, and provide useful intuition in applications. Together with other “fluctuation” quantities related to passage over a level, such as the overshoot of the level, and various undershoots, etc., it constitutes one of many well known properties of the renewal theory of random walks. More generally, properties such as stability of the passage time, etc., have been extended to random walks on the line. (References and further discussion are given later.)

It is natural to consider carrying the discrete time results over to a Lévy process \( (X_t)_{t \geq 0} \), and this has been done in the literature for some of the fluctuation quantities, especially, see [17] for stability of the overshoot. Applications of this and related kinds of result abound; we have in mind, in particular, applications to the insurance risk process: see, e.g., recent results in [5], [15], [19], [28], and [31]. These authors have tended to concentrate on properties of the overshoot and undershoots, with less attention paid to the ruin time, \( \tau_u \). But it could be argued that \( \tau_u \) is the most important or at least the most interesting variable, from a practical point of view.

Our aim in this paper is to set out in detail a comprehensive listing of conditions for the stability of \( \tau_u \), in the Lévy setting. For “large time” stability, i.e., as \( u \to \infty \), the discrete time (random walk) results can be consulted to give useful guidance for some of the Lévy results; others are rather straightforward to transfer, but others again are challenging. We consider both stability in probability and almost sure (a.s.) stability of \( \tau_u/u \), as \( u \to \infty \), when \( \lim \sup_{t \to \infty} X_t = \infty \) a.s., and \( \lim_{t \to \infty} X_t = -\infty \) a.s.

Even more interesting is the “small time” stability, i.e., as \( u \to 0 \), of the passage time. Here there are of course no corresponding random walks that can be used for guidance, but, remarkably, small time results for Lévy processes often parallel large time results in certain ways. With this insight and some further analysis we are able to give also a comprehensive analysis of the small time stability of \( \tau_u \). Some curious and unexpected results occur (see, e.g., Remark 2.3). Such results may be thought of as adding to our understanding of the local properties of Lévy processes.

The setting is as follows. Suppose that \( X = \{X_t : t \geq 0\} \), \( X_0 = 0 \), is a Lévy process defined on \((\Omega, \mathcal{F}, P)\), with triplet \((\gamma, \sigma^2, \Pi_X)\), \( \Pi_X \) being the Lévy measure of \( X \), \( \gamma \in \mathbb{R} \), and \( \sigma^2 \geq 0 \). Thus the characteristic function of \( X \) is given by the Lévy-Khintchine representation, \( E(e^{i\theta X_t}) = e^{t\Psi_X(\theta)} \), where

\[
\Psi_X(\theta) = i\theta \gamma - \sigma^2 \theta^2 / 2 + \int_{\mathbb{R}} (e^{i\theta x} - 1 - i\theta x 1_{\{|x| \leq 1\}}) \Pi_X(dx), \quad \text{for } \theta \in \mathbb{R}.
\] (1.1)
Denote the maximum process by
\[ X_t = \sup_{0 \leq s \leq t} X_s, \]
and let
\[ G_t = \sup\{0 \leq s \leq t : X_s = X_t\} \]
be the time of the last maximum prior to time \( t \). Our focus will be on the first passage time above level \( u \), defined by
\[ \tau_u = \inf\{t \geq 0 : X_t > u\}, \quad u > 0. \]
(We adopt the convention that the inf of the empty set is \( +\infty \).) Also important will be the time of the last maximum before passage, \( G_{\tau_u} \), and the position after transit above level \( u \), \( X_{\tau_u} \). Throughout, we assume that \( \Pi_X \) is not identically zero and that \( X \) is not the negative of a subordinator (in which case \( \tau_u = \infty \) for all \( u > 0 \)). By a compound Poisson process we will mean a Lèvy process with finite Lèvy measure, no Brownian component and zero drift.

We need some further notation. Let \((L^{-1}_t, H_t)_{t \geq 0}\) denote the bivariate ascending inverse local time–ladder height subordinator process of \( X \). The process \((L^{-1}_t, H_t)\) is defective when, and only when, \( \lim_{t \to \infty} X_t = -\infty \) a.s. In that case, it is obtained from a nondefective process \((\check{L}^{-1}_t, \check{H}_t)\) by exponential killing with rate \( q > 0 \), say. When \((L^{-1}_t, H_t)\) is nondefective the killing is unnecessary and we set \((L^{-1}_t, H_t) = (L^{-1}_t, H_t)\) and take \( q = 0 \). We denote the bivariate Lèvy measure of \((L^{-1}_t, H_t)_{t \geq 0}\) by \( \Pi_{L^{-1}_t, H_t}(\cdot, \cdot) \), and let \( \Pi_{L^{-1}} \) and \( \Pi_H \) be the marginal Lèvy measures of \( L^{-1} \) and \( H \). The Laplace exponent \( \kappa(a, b) \) of \((L^{-1}_t, H_t)\) will play an important role in our analysis. It is defined by
\[ e^{-\kappa(a,b)} = e^{-q} e^{-a \check{L}^{-1}_t - b \check{H}_t}, \quad (1.2) \]
for values of \( a, b \in \mathbb{R} \) for which the expectation is finite. We can write
\[ \kappa(a,b) = q + d_{L^{-1}} a + d_H b + \int_{t \geq 0} \int_{h \geq 0} (1 - e^{-at - bh}) \Pi_{L^{-1}, H}(dt, dh), \quad (1.3) \]
where \( d_{L^{-1}} \geq 0 \) and \( d_H \geq 0 \) are drift constants. See, e.g., [7], [14], [29], [33], for these relationships.

The following theorem connects the Laplace transform of the fluctuation quantities with the bivariate Laplace exponent. It is an extension of the “second factorisation identity” ([32], Eq. (3.2)). A proof of Theorem 1.1 is in [22].

**Theorem 1.1.** (Laplace Transform Identity.) Fix \( \mu > 0, \rho \geq 0, \lambda \geq 0, \nu \geq 0, \theta \geq 0 \). If \( \mu + \lambda \neq \rho \),
\[ \int_{u \geq 0} e^{-\mu a} E\left(e^{-\rho (X_{\tau_u} - u) - \lambda (u - X_{\tau_u}) - \nu G_{\tau_u} - \theta (\tau_u - G_{\tau_u})}; \tau_u < \infty \right) du = \frac{\kappa(\theta, \mu + \lambda) - \kappa(\theta, \rho)}{\mu + \lambda - \rho} \kappa(\nu, \mu). \quad (1.4) \]
In the present paper we apply these concepts to study the stability of the passage time, $\tau_u$, by which we mean that $\tau_u/u$ has a finite and positive nonstochastic limit, where the convergence may be as $u \to 0$ or $u \to \infty$, and the convergence may be in probability, almost sure (a.s.), or in mean. We will also consider, to a lesser extent, the position, $X_{\tau_u}$, of $X$ as it crosses the boundary. Some other results of interest, especially, that $\tau_u/u$ are uniformly integrable as $u \to \infty$ if $X$ has a finite positive mean (see Lemma 5.2) are derived as by-products.

The results relating to stability of $\tau_u$ are given in Section 2. In contrast, in Section 3 we consider large time conditional stability of $\tau_u$ when $P(\tau_u < \infty) \to 0$ as $u \to \infty$. This is the usual setup in the Lévy insurance risk model, for which see, e.g., [4], [3], [15] and [28] for background and references. Section 4 contains some concluding remarks and references. All proofs are in Sections 5, 6, and the Appendix.

2. Stability

This section contains results relating to the stability of $\tau_u$ as $u \to L$ where $L = \infty$ or $L = 0$. For stability to make sense when $L = \infty$ we need, at a minimum, to assume that $P(\tau_u < \infty) \to 1$ as $u \to \infty$. This is equivalent to \( \limsup_{t \to \infty} X_t = +\infty \) a.s., in which case $\tau_u < \infty$ a.s. for all $u > 0$ and $\tau_u \to \infty$ a.s. as $u \to \infty$.

The natural analogue of this condition when $L = 0$ is that $P(\tau_u < \infty) \to 1$ and $\tau_u \to 0$ a.s. as $u \downarrow 0$. This is equivalent to $0$ being regular for $(0, \infty)$; see [8] for an analytic equivalence. Thus the overriding assumptions throughout this section are: $\limsup_{t \to \infty} X_t = +\infty$ a.s. when $L = \infty$, and $0$ is regular for $(0, \infty)$ when $L = 0$.

Let $\Pi_X$ and $\Pi_X^\pm$ denote the tails of $\Pi_X$, thus

$$\Pi_X^+(x) = \Pi_X((x, \infty]), \quad \Pi_X^-(x) = \Pi_X((-\infty, -x]), \quad \text{and} \quad \Pi_X(x) = \Pi_X^+(x) + \Pi_X^-(x),$$

(2.1)

for $x > 0$, and define a kind of truncated mean

$$A(x) := \gamma + \Pi_X^+(1) - \Pi_X^-(1) + \int_1^x \left( \Pi_X^+(y) - \Pi_X^-(y) \right) dy = \gamma + x \left( \Pi_X^+(x) - \Pi_X^-(x) \right) + \int_{1 < |y| \leq x} y \Pi_X(dy), \quad x > 0.$$  

(2.2)

The first theorem concerns the stability in probability of $\tau_u$. Consider first stability for large times, as $u \to \infty$, i.e., the property $\tau_u/u \overset{P}{\to} 1/c$ as $u \to \infty$, for some $c \in (0, \infty)$. This is equivalent to the relative stability in probability of the process $X$ itself, i.e., to $X_t/t \overset{P}{\to} c$ as $t \to \infty$. We prove it via an equivalence of the stability of $\tau_u$ with that of $\overline{X}$, namely, $\overline{X}_t/t \overset{P}{\to} c$ as $t \to \infty$, a trivial relationship. We then show that the latter holds iff $X$ is relatively stable, which is not entirely obvious, but follows from similar (large time)
random walk working of [27], where the stability of the passage time of a random walk above a constant level is considered for general norming sequences. The stability of \( \tau_u \) is connected to the bivariate Laplace exponent in (2.4), which is a new relationship, derived via Theorem 1.1, and the list of equivalences for this case is completed by that of (2.6) and (2.7), which is in Theorem 3.1 of [16].

This list, for the case \( u \to \infty, c \in (0, \infty) \), then sets the pattern we work from for the case \( u \downarrow 0, c \in (0, \infty) \), and later results. Theorem 2.1 also considers the cases \( c = 0 \) and \( c = \infty \) for completeness, though these strictly speaking do not give rise to stability conditions.

**Theorem 2.1.** (Stability in Probability of the Exit Time.) (a) Fix a constant \( c \in (0, \infty) \) and let \( L = 0 \) or \( \infty \) \((1/L = \infty \) or \( 0 \)). Then the following are equivalent:

\[
\frac{\tau_u}{u} \xrightarrow{P} \frac{1}{c}, \text{ as } u \to L; \tag{2.3}
\]

\[
\lim_{x \to 1/L} \frac{\kappa(x,0)}{\kappa(x,\xi x)} = \frac{1}{1 + \xi c}, \text{ for each } \xi > 0; \tag{2.4}
\]

\[
\frac{X_t}{t} \xrightarrow{P} c, \text{ as } t \to L; \tag{2.5}
\]

\[
X_t \xrightarrow{P} c, \text{ as } t \to L. \tag{2.6}
\]

In the case \( L = \infty \), (2.3)–(2.6) are equivalent to

\[
x \Pi_X(x) \to 0 \text{ and } A(x) \to c, \text{ as } x \to \infty. \tag{2.7}
\]

In the case \( L = 0 \), (2.3)–(2.6) are equivalent to

\[
\sigma^2 = 0, \text{ } x \Pi_X(x) \to 0 \text{ and } A(x) \to c, \text{ as } x \downarrow 0. \tag{2.8}
\]

(b) Suppose \( c = 0 \). If \( L = \infty \) then (2.3)–(2.7) remain equivalent. If \( L = 0 \) then (2.3)–(2.5) remain equivalent, as do (2.6) and (2.8). However while (2.6) implies (2.3)–(2.5), the converse does not hold.

(c) Suppose \( c = \infty \). Then (2.3)–(2.5) remain equivalent for \( L = 0 \) or \( \infty \) in the following sense:

\[
\frac{\tau_u}{u} \xrightarrow{P} 0, \text{ as } u \to L, \text{ iff } \lim_{x \to 1/L} \frac{\kappa(x,0)}{\kappa(x,\xi x)} = 0, \text{ for each } \xi > 0, \text{ iff } \frac{X_t}{t} \xrightarrow{P} \infty, \text{ as } t \to L. \tag{2.9}
\]

Again, while (2.6) implies (2.3)–(2.5), it is not equivalent in either case, \( L = 0 \) or \( \infty \).

**Remark 2.1.** As mentioned above, the equivalence of (2.6) and (2.7) when \( L = \infty \) is in [16], while the equivalence of (2.6) and (2.8) when \( L = 0 \) is in Theorem 2.1 of [16]. Both of these results hold for all \( c \in (-\infty, \infty) \). We include them in the statement of Theorem 2.1 for completeness and for the convenience of the reader.
The next theorem concerns the almost sure stability of \( \tau_u \). We follow the pattern set by Theorem 2.1. The connection with the bivariate Laplace exponent is transmuted in this case to requiring finite first moments of the ladder processes \( H \) and \( L^{-1} \). Almost sure stability for large times requires a finite positive mean for \( X \) (for large times), and bounded variation with positive drift of \( X \) (for small times). Recall that when \( X \) is of bounded variation, we may write the Lévy-Khintchine exponent in the form

\[
\Psi(\theta) = i\theta dX + \int_{\mathbb{R}} (e^{i\theta x} - 1) \Pi_X(dx),
\]

where \( dX = \gamma - \int x 1_{|x| \leq 1} \Pi_X(dx) \) is called the drift of \( X \).

**Theorem 2.2.** (Almost Sure Stability of the Exit Time.)

(a) Fix \( c \in [0, \infty) \).

(i) We have \( \frac{\tau_u}{u} \to \frac{1}{c} \), a.s. as \( u \to \infty \) iff \( E|X_1| < \infty \) and \( EX_1 = c \geq 0 \).

(ii) We have \( \frac{\tau_u}{u} \to \frac{1}{c} \), a.s. as \( u \to 0 \) iff \( X \) is of bounded variation with drift \( dX = c \geq 0 \).

(b) Fix \( c \in (0, \infty) \). Then (i) holds iff \( EH_1 < \infty \) and \( EL^{-1}_1 < \infty \), in which case \( c = EH_1/EL^{-1}_1 \), while (ii) holds iff \( \sigma^2 = 0 \), \( d_{L^{-1}} > 0 \) and \( d_H > 0 \), in which case \( c = d_H/d_{L^{-1}} \).

**Remark 2.2.** Note that, under (2.7) and (2.8) respectively,

\[
\lim_{x \to \infty} A(x) = \gamma + \int_{|y| > 1} y \Pi_X(dy) \quad \text{and} \quad \lim_{x \downarrow 0} A(x) = \gamma - \int_{0 < |y| \leq 1} y \Pi_X(dy).
\]

Here existence of the limits is equivalent to conditional convergence of the integrals. Under the conditions of parts (a)(i) and (a)(ii) of Theorem 2.2, these integrals converge absolutely and the limits are then given by \( EX_1 \) and \( d_X \) respectively, thus confirming that the expressions for \( c \) in Theorems 2.1 and 2.2 agree. The difference between (2.7) and (2.8) and (i) and (ii) of Theorem 2.2 is essentially whether the integrals in (2.11) converge conditionally or absolutely.

In the next theorem we examine the convergence of \( E\tau_u/u \) as \( u \to \infty \) and as \( u \downarrow 0 \). Recall that \( E\tau_u < \infty \) for some, hence all, \( u \geq 0 \), iff \( X \) drifts to \(+\infty\) a.s., iff \( E L^{-1}_1 < \infty \) (see, e.g., Theorem 1 of [18]).

**Theorem 2.3.** (Stability of the Expected Exit Time.) (a) Fix \( c \in (0, \infty) \). Then

(i) \( E\tau_u < \infty \) for each \( u > 0 \) and \( \lim_{u \to \infty} \frac{E\tau_u}{u} = \frac{1}{c} \) iff \( 0 < EX_1 \leq E|X_1| < \infty \). In this situation, \( EH_1 < \infty \), \( EL^{-1}_1 < \infty \), and \( c = EX_1 = EH_1/EL^{-1}_1 \).

(ii) \( E\tau_u < \infty \) for each \( u > 0 \) and \( \lim_{u \downarrow 0} \frac{E\tau_u}{u} = \frac{1}{c} \) iff \( EL^{-1}_1 < \infty \) and \( d_H > 0 \), and then \( c = d_H/EL^{-1}_1 \).

(b) (The case \( c = 0 \)) (i) In Part (i) of the theorem, the case \( c = 0 \) cannot arise; when \( E\tau_u < \infty \) for each \( u > 0 \), \( \lim_{u \to \infty} E\tau_u/u \) exists and is in \([0, \infty)\).
(ii) We have $E\tau_u < \infty$ for each $u > 0$, and $\lim_{u \downarrow 0} E\tau_u / u = \infty$ iff $EL_1^{-1} < \infty$ and $d_H = 0$.

(c) (The case $c = \infty$) (i) We have $E\tau_u < \infty$ for each $u > 0$ and $\lim_{u \to \infty} E\tau_u / u = 0$ iff $EL_1^{-1} < \infty$ and $EH_1 = \infty$.

(ii) In Part (ii) of the theorem, the case $c = \infty$ cannot arise; when $E\tau_u < \infty$ for each $u > 0$, we always have $\liminf_{u \downarrow 0} E\tau_u / u > 0$.

Remark 2.3. (i) It is curious that the formula for $c$ in Part (a)(ii) of Theorem 2.3 doesn’t agree with the versions in Theorem 2.1 or Theorem 2.2. We give an example to illustrate how the difference can arise. Let

$$X_t = at - N_t$$

where $N_t$ is a rate one Poisson process and $a > 1$. Thus $\lim_{t \to \infty} X_t = \infty$ a.s. Since $\tau_u = ua^{-1}$ for sufficiently small $u$, it trivially follows that

$$\lim_{u \downarrow 0} \frac{\tau_u}{u} = \frac{1}{a} \text{ a.s.}$$

We claim that

$$\frac{E\tau_u}{u} \to \frac{1}{a} + \frac{E\tau_1}{a}. \quad (2.12)$$

This is because, if $\xi$ is the time of the first jump of $N$, then

$$E\tau_u = E(\tau_u; N_{ua^{-1}} = 0) + E(\tau_u; N_{ua^{-1}} \geq 1)$$

$$= ua^{-1}e^{-ua^{-1}} + \int_0^{ua^{-1}} E(\tau_u | \xi = t)P(\xi \in dt)$$

$$= ua^{-1}e^{-ua^{-1}} + \int_0^{ua^{-1}} (t + E\tau_{1-at+u})e^{-t}dt.$$

Since $\tau_{1+x} \overset{P}{\to} \tau_1$ as $x \downarrow 0$, (2.12) now follows after dividing by $u$ and taking the limit.

We now check that this agrees with Part (ii) of Theorem 2.3. For the normalisation of $L$, the local time at the maximum, we take

$$L_t = \int_0^t I(X_s = \bar{X}_s) \, ds.$$ 

Then the ladder height process is linear drift, $H_t = at$. Hence $d_H = a$. By construction

$$L_t^{-1} = t + \sum_{i=1}^{N_t} R_i$$

where again $N_t$ is a rate one Poisson process and $R_i$ are iid random variables independent of $N$, with distribution the same as that of $\tau_1$. Hence $d_{L^{-1}} = 1$ and

$$EL_1^{-1} = 1 + E\tau_1,$$
so the $c$ in Part (ii) of Theorem 2.3 is $d_H/EL_1^{-1} = a/(1 + E\tau_1)$, giving agreement with (2.12). On the other hand, the $c$ in Part (ii) of Theorem 2.2 is $d_X = d_H/d_{L^{-1}} = a$.

We now turn to stability of the time of the last maximum before ruin. As may be expected, this is a more difficult object to study than $\tau_u$. We consider the three modes of convergence investigated in Theorems 2.1–2.3.

**Theorem 2.4. (Stability of the Last Maximum before Ruin.)** Let $L = 0$ or $\infty$ $(1/L = \infty$ or $0)$.

(a) Fix $c \in (0, \infty)$. We have

\[
\frac{G_{\tau_u}}{u} \xrightarrow{P} \frac{1}{c}, \text{ as } u \to L,
\]

if and only if

\[
\lim_{x \to 1/L} \frac{\kappa(0, x)}{\kappa(\xi x, x)} = \frac{c}{c + \xi}, \text{ for each } \xi > 0.
\]

(b) Fix $c \in [0, \infty)$. (i) $\frac{G_{\tau_u}}{u} \to \frac{1}{c}$, a.s. as $u \to \infty$ iff $E|X_1| < \infty$ and $EX_1 = c \geq 0$.

(ii) $\frac{G_{\tau_u}}{u} \to \frac{1}{c}$, a.s., as $u \to 0$ iff $X$ is of bounded variation with drift $d_X = c \geq 0$.

(c) If $0 < EX_1 < \infty$ then $\lim_{u \to \infty} \frac{EG_{\tau_u}}{u} = \frac{1}{EX_1}$.

**Remark 2.4.** It’s not clear how the conditions of Theorem 2.1 relate to the stability in probability of $G_{\tau_u}$. We can show that (2.3)–(2.7) imply (2.13) and (2.14) but it’s not clear whether or not the converse holds. For almost sure convergence the results for $G_{\tau_u}$ parallel those for $\tau_u$. For convergence in mean the situation remains largely unresolved.

The final result, Theorem 2.5, belongs in the present section since it holds in a case when $\lim_{t \to \infty} X_t = +\infty$ a.s., but we apply it in the next section, in the case when $\lim_{t \to \infty} X_t = -\infty$ a.s., to obtain results in the Lévy insurance risk model.

**Theorem 2.5. (Convergence of Expected Exit Times with Overshoot.)** Assume $0 < EX_1 \leq E|X_1| < \infty$, and that $X$ is not compound Poisson, or is compound Poisson with a nonlattice jump distribution. Then for all $\rho > 0$

\[
\lim_{u \to \infty} E\left(\frac{G_{\tau_u}}{u}e^{-\rho(X_{\tau_u} - u)}\right) = \lim_{u \to \infty} E\left(\frac{\tau_u}{u}e^{-\rho(X_{\tau_u} - u)}\right) = \frac{1}{EX_1}Ee^{-\rho Y},
\]

where $Y$ is the limiting distribution of the overshoot $X_{\tau_u} - u$. $Y$ has density $\Pi H(h)dh/EH_1$ on $(0, \infty)$, and mass $d_H/EH_1$ at 0.
3. Stability In the Insurance Risk Model

The aim of this section is to illustrate that stability questions are also of interest when $X_t \to -\infty$ a.s. as $t \to \infty$. We phrase the discussion in terms of an insurance risk model. In this case $X$ represents the excess in claims over premium of an insurance company. The classical model in this context is the Cramér-Lundberg model in which $X$ is the sum of a compound Poisson process with positive jumps, representing claims, and a negative drift, representing premium inflow. The results in the present section will be given for a general Lévy insurance risk model where no such restrictions are placed on $X$.

The over-riding assumption throughout this section is the Cramér condition, namely, that

$$Ee^{\nu_0 X_1} = 1,$$

for some $\nu_0 > 0$. (3.1)

It’s well known that, under (3.1), $EX_1$ is well defined, with $EX_1 < \infty$, $EX_1^{-} \in (0, \infty]$, and $EX_1 \in [-\infty, 0)$, and so $\lim_{t \to \infty} X_t = -\infty$ a.s. Further, $E(X_1 e^{\nu X_1})$ is finite and positive for all $\nu$ in a left neighbourhood of $\nu_0$, and

$$\mu^* := E(X_1 e^{\nu_0 X_1}) > 0 \quad (\text{possibly } \mu^* = +\infty).$$

(3.2)

Since $\lim_{t \to \infty} X_t = -\infty$ a.s., we are in the situation that $P(\tau_u < \infty) < 1$ for all $u > 0$, and $\lim_{u \to \infty} P(\tau_u < \infty) = 0$. In an insurance risk context, we are interested in forecasting the ruin time $\tau_u$ in a worst case scenario, i.e., conditional on $\tau_u < \infty$ ("ruin occurs"). Asymptotic properties of $\tau_u$ and associated variables, conditional on $\tau_u < \infty$, often provide surprisingly good approximations of corresponding finite level distributions; cf, e.g., [20]. In the present context we look at the stability of $\tau_u$, $G_{\tau_u}$ and $X_{\tau_u}$, showing they are asymptotically linear under mild conditions.

We need some more infrastructure. Let $(X_t^*)_{t \geq 0}$ denote the Esscher transform of $X$ defined by

$$P((X_s^*, 0 \leq s \leq t) \in B, X_t^* \in dx) = e^{\nu_0 x} P((X_s, 0 \leq s \leq t) \in B, X_t \in dx),$$

(3.3)

for any Borel subset $B$ of $\mathbb{R}^{[0,t]}$. Equivalently $X^*$ may be introduced by means of exponential tilting; that is, define a new probability $P^*$, given on $\mathcal{F}_t$ by

$$\frac{dP^*}{dP} = e^{\nu_0 X_t}.$$ 

(3.4)

Then $X$ under $P^*$ has the same distribution as $X^*$ under $P$. It easily follows that

$$Ef(X_t^*) = E^* f(X_t) = E(f(X_1) e^{\nu_0 X_1}),$$

where $\nu_0 > 0$. (3.5)
for any Borel function \( f \) for which the expectations are finite. \( X^* \) is itself a Lévy process with exponent 
\[
\Psi(\theta - i\nu_0) \text{ and } E^*X_1 = \mu^*. \]
Since \( \mu^* > 0 \) by (3.2), \( X^*_t \) drifts to \(+\infty\) a.s., and hence \((H^*_t)_{t \geq 0}\), the increasing 
ladder height process associated with \((X^*_t)_{t \geq 0}\), is proper.

Our setup is that of Bertoin and Doney [9]. The main result in [9], which we give in the form proved in 
Theorem 7.6 of [29], see also Section XIII.5 of [3], is: Suppose (3.1) holds and the support of \( \Pi_X \) is non-lattice 
in the case that \( X \) is compound Poisson. Then
\[
\lim_{u \to \infty} e^{\nu_0 u} P(\tau_u < \infty) = C \in [0, \infty),
\]
where \( C := E^*e^{-\nu_0 Y} > 0 \) if and only if \( \mu^* < \infty \). Here \( Y \) is the limiting distribution of the overshoot \( X_{\tau_u} - u \) under \( P^* \).

To state the stability result for the general Lévy insurance risk model under (3.1), introduce the probability 
measure \( P(u)(\cdot) = P(\cdot | \tau_u < \infty) \), and denote convergence in probability conditional on \( \tau_u < \infty \) by \( p(u) \to \).

**Theorem 3.1.** Assume (3.1) holds and \( \mu^* < \infty \) (so that \( 0 < \mu^* < \infty \)). Then, as \( u \to \infty \),
\[
\frac{X_{\tau_u}}{u} p(u) \to 1, \quad \frac{G_{\tau_u}}{u} p(u) \to \frac{1}{\mu^*} \quad \text{and} \quad \frac{\tau_u}{u} p(u) \to \frac{1}{\mu^*}.
\]

Assume in addition that the support of \( \Pi_X \) is non-lattice in the case that \( X \) is compound Poisson. Then
\[
\lim_{u \to \infty} \frac{E^{(u)}X_{\tau_u}}{u} = 1, \quad \lim_{u \to \infty} \frac{E^{(u)}G_{\tau_u}}{u} = \frac{1}{\mu^*} \quad \text{and} \quad \lim_{u \to \infty} \frac{E^{(u)}\tau_u}{u} = \frac{1}{\mu^*}.
\]

Parts of our Theorem 3.1 are well known for the Cramér-Lundberg model, and their extension to the 
general Lévy insurance risk model is straightforward. Others appear to be new.

4. Concluding Remarks

There is of course a very large literature on (large time) renewal theorems for random walks, and, more 
recently, some similar results have been proved for Lévy processes. Regarding the ruin time, most results so 
far concern the infinite horizon ruin probability, \( P(\tau_u < \infty) \), or, equivalently, the distribution of the overall 
maximum of the random walk or Lévy process, and we do not attempt to summarise them here (other than 
the references mentioned in Sections 1–3). A web search turns up many such papers and books.

The finite horizon ruin probability, \( P(\tau_u < T) \), is less studied, but important results are obtained in, 
e.g., [2], [5], [26], [6], [25], [12] (see also their references), and especially, in the insurance/actuarial literature 
(usually from a more applied point of view). These results of course give information on the long run
distribution of the ruin time, conditional on ruin occurring. A more recent result along these lines is in [21], assuming, like [12] and [25], convolution equivalent conditions on the tails of the process or its Lévy measure. These authors are interested in the asymptotic distribution of \( \tau_u \), rather than in its stability per se; as mentioned earlier, results on stability such as we give are more akin to classical (large time) renewal theory than to these, and small time versions, which make sense for Lévy processes but not for random walks, have previously been neglected, in the main.

We turn now to the proofs.

5. Proofs for Section 2

We assume throughout this section that \( \limsup_{t \to \infty} X_t = +\infty \) a.s. when \( L = \infty \), and 0 is regular for \((0, \infty)\) when \( L = 0 \). In the former case, \( \tau_u < \infty \) a.s. for all \( u > 0 \), while \( P(\tau_u < \infty) \to 1 \) as \( u \to 0 \) in the latter case.

**Proof of Theorem 2.1.** (a) and (b). Let \( c \in [0, \infty) \) until further notice, with the obvious interpretations when \( c = 0 \). Assume (2.3) holds with \( u \to L \). From (1.4) we have, for \( u > 0, \theta > 0, \mu \int_{u \geq 0} e^{-\mu u} E \left( e^{-\theta \tau_u}; \tau_u < \infty \right) du = 1 - \frac{\kappa(\theta, 0)}{\kappa(\theta, \mu)} \). \hfill (5.1)

Take \( y > 0 \) and replace \( \mu \) by \( \mu/y \), \( u \) by \( uy \), and \( \theta \) by \( \theta/y \) in this to get

\[
\mu \int_{u \geq 0} e^{-\mu u} E \left( e^{-\theta \tau_{uy}/y}; \tau_{uy} < \infty \right) du = 1 - \frac{\kappa(\theta/y, 0)}{\kappa(\theta/y, \mu/y)}.
\hfill (5.2)
\]

By hypothesis, \( \tau_{uy}/y \xrightarrow{D} u/c \) as \( y \to L \) for each \( u > 0 \), so letting \( y \to L \) in (5.2) gives, by dominated convergence,

\[
\lim_{y \to L} \frac{\kappa(\theta/y, 0)}{\kappa(\theta/y, \mu/y)} = 1 - \mu \int_{u \geq 0} e^{-\mu u} e^{-\theta u/c} du = \frac{\theta}{\theta + \mu c}.
\]

Replacing \( y \) by \( x = \theta/y \to 1/L \) and \( \mu/\theta \) by \( \xi \) gives (2.4) with \( x \to 1/L \).

Conversely, assume (2.4) with \( x \to 1/L \). Then from (5.2) we see that, for \( \theta > 0 \),

\[
\lim_{y \to L} \mu \int_{u \geq 0} e^{-\mu u} E \left( e^{-\theta \tau_{uy}/y}; \tau_{uy} < \infty \right) du = \frac{\mu c}{\theta + \mu c}.
\]

For each \( y > 0, \theta > 0 \), the function \( f_y(u, \theta) := E \left( e^{-\theta \tau_{uy}/y}; \tau_{uy} < \infty \right) \) is monotone decreasing in \( u \) and bounded by 1. Given any sequence \( y_k \to L \) we can by Helly’s theorem find a subsequence \( \tilde{y}_k \to L \), possibly
depending on θ but not on u, such that $f_{\tilde{y}_k}(u, \theta) \to \tilde{f}(u, \theta)$ for some function $\tilde{f}(u, \theta) \in [0, 1]$. Then by dominated convergence we have

$$
\mu \int_{u \geq 0} e^{-\mu u} \tilde{f}(u, \theta) du = \frac{\mu c}{\theta + \mu c} \mu \int_{u \geq 0} e^{-\mu u - \theta u / c} du,
$$

and from the uniqueness of Laplace transforms we deduce that $\tilde{f}(u, \theta) = e^{-\theta u / c}$, not dependent on the choice of subsequence. Hence (taking $u = 1$ now)

$$
\lim_{y \to L} \mu \int_{u \geq 0} e^{-\theta u / y} \tilde{f}(u, \theta) du = \mu c \theta + \mu c = \mu \int_{u \geq 0} e^{-\mu u} e^{-\theta u / c} du,
$$

and from the uniqueness of Laplace transforms we deduce that $\tilde{f}(u, \theta) = e^{-\theta u / c}$, not dependent on the choice of subsequence. Hence (taking $u = 1$ now)

$$
\lim_{y \to L} E \left( e^{-\theta \tau_u / y}; \tau_u < \infty \right) = e^{-\theta / c}, \theta > 0,
$$

proving (2.3) with $u \to L$.

Since

$$
\{\tau_u > t\} \subseteq \{X_t \leq u\} \subseteq \{\tau_u \geq t\}, \ t > 0, u > 0,
$$

we easily see that (2.3) is equivalent to (2.5) in either case, $L = \infty$ or $L = 0$, for $c \geq 0$.

Next we show (2.6) implies (2.5). First consider the case $L = \infty$. By Theorem 3.1 of [16], (2.6) with $t \to \infty$ is equivalent to (2.7), and the first relation in (2.7) implies

$$
\lim_{x \to \infty} \frac{V(x)}{x} = 0,
$$

(5.4)

where

$$
V(x) := \sigma^2 + \int_{|y| \leq x} y^2 \Pi X(dy).
$$

To deduce (2.5) from (2.7) and (5.4) in the case $L = \infty$, decompose $X$ into small and large jump components as in Lemma 6.1 of [16] to get

$$
X_s = s\nu(t) + \sigma B_s + X_s^{(1)} + X_s^{(2)}, \ 0 \leq s \leq t,
$$

where

$$
\nu(x) := \gamma + \int_{1 < |y| \leq x} y \Pi X(dy), \ x > 0,
$$

$\sigma B_s + X_s^{(1)}$ is a mean 0 martingale with jumps bounded in modulus by $t$ and all moments finite, and

$$
X_s^{(2)} = \sum_{0 < r \leq s} \Delta X_r 1(\Delta X_r > t).
$$

By Doob’s inequality, for $\varepsilon > 0$,

$$
P \left( \sup_{0 \leq s \leq t} |\sigma B_s + X_s^{(1)}| > \varepsilon t \right) \leq \frac{1}{(\varepsilon t)^2} E(\sigma B_t + X_t^{(1)})^2 = \frac{1}{\varepsilon^2 t} V(t),
$$

where

$$
V(t) := \sigma^2 + \int_{|y| \leq t} y^2 \Pi X(dy).
$$

To deduce (2.5) from (2.7) and (5.4) in the case $L = \infty$, decompose $X$ into small and large jump components as in Lemma 6.1 of [16] to get

$$
X_s = s\nu(t) + \sigma B_s + X_s^{(1)} + X_s^{(2)}, \ 0 \leq s \leq t,
$$

where

$$
\nu(x) := \gamma + \int_{1 < |y| \leq x} y \Pi X(dy), \ x > 0,
$$

$\sigma B_s + X_s^{(1)}$ is a mean 0 martingale with jumps bounded in modulus by $t$ and all moments finite, and

$$
X_s^{(2)} = \sum_{0 < r \leq s} \Delta X_r 1(\Delta X_r > t).
$$

By Doob’s inequality, for $\varepsilon > 0$,

$$
P \left( \sup_{0 \leq s \leq t} |\sigma B_s + X_s^{(1)}| > \varepsilon t \right) \leq \frac{1}{(\varepsilon t)^2} E(\sigma B_t + X_t^{(1)})^2 = \frac{1}{\varepsilon^2 t} V(t),
$$

where

$$
V(t) := \sigma^2 + \int_{|y| \leq t} y^2 \Pi X(dy).
$$
and this tends to 0 as $t \to \infty$ by (5.4). Also

$$P\left(\sup_{0 \leq s \leq t} |X_s^{(2)}| = 0\right) \geq P(\text{no jumps with } |\Delta X_s| > t \text{ occur by time } t) = \exp(-t\Pi_X(t)) \to 1,$$

as $t \to \infty$, while

$$\nu(t) = A(t) - t\Pi^+(t) + t\Pi^-(t) \to c,$$

both by (2.7). Thus we have $P(\sup_{0 \leq s \leq t} |X_s - cs| > \varepsilon t) \to 0$ as $t \to \infty$, which implies (2.5) with $L = \infty$ and $c \geq 0$.

Next we deal with the implication (2.6) implies (2.5) in the case $L = 0$. Note that, by Theorem 2.1 of [16], (2.6) with $t \downarrow 0$ is equivalent to (2.8), and the first and second relations in (2.8) imply

$$V(x) = \frac{2}{x} \int_0^x y\Pi_X(y)dy + x\Pi_X(x) = \frac{2}{x} \int_0^x o(1)dy + o(1) = o(1), \text{ as } x \downarrow 0. \quad (5.5)$$

This takes the place of (5.4) in the $L = 0$ case, and the rest of the proof that (2.6) implies (2.5) with $L = 0$ is virtually the same as for the case with $t \to \infty$.

We have left to show that (2.5) implies (2.6) except when $c = L = 0$. This is obvious if $c = 0$ and $L = \infty$ so suppose $c > 0$. Note that, for $t > 0$,

$$X_{2t} = X_t \vee \left(\sup_{t < s \leq 2t} X_s\right)$$

$$= X_t \vee \left(\sup_{t < s \leq 2t} (X_s - X_t)\right)$$

$$= X_t \vee \left(X_t + X_t'\right),$$

where $X_t'$ is an independent copy of $X_t$. Consequently, for $\varepsilon \in (0, c/3)$, as $t \to L$,

$$o(1) = P(X_{2t} \leq (c - \varepsilon)2t) = P(X_t \vee \left(X_t + X_t'\right) \leq (c - \varepsilon)2t)$$

$$\geq P(X_t \leq (c - \varepsilon)2t, X_t + (c + \varepsilon)t \leq (c - \varepsilon)2t, |X_t - ct| \leq \varepsilon t)$$

$$= P\left(\frac{X_t}{t} \leq 2(c - \varepsilon), \frac{X_t}{t} \leq c - 3\varepsilon\right) P\left(\frac{|X_t|}{t} - c \leq \varepsilon\right)$$

$$\geq \left(P\left(\frac{X_t}{t} \leq c - 3\varepsilon\right) - P\left(\frac{X_t}{t} > 2(c - \varepsilon)\right)\right)(1 + o(1))$$

$$= \left(P\left(\frac{X_t}{t} \leq c - 3\varepsilon\right) - o(1)\right)(1 + o(1)).$$

This shows that $P(X_t > (c - 3\varepsilon)t) \to 1$, and since also

$$P\left(\frac{X_t}{t} \leq c + \varepsilon\right) \geq P\left(\frac{X_t}{t} \leq c + \varepsilon\right) \to 1,$$
we have \( X_t / t \xrightarrow{P} c \). Hence (2.5) implies (2.6) for \( L = 0 \) or \( L = \infty \).

(c) The equivalences in (2.9) follow by the same methods as used in Part (a), and clearly (2.6) in case \( c = \infty \) implies (2.5) in case \( c = \infty \).

All that remains is to give counterexamples showing (2.5) does not imply (2.6) when \( c = L = 0 \) or when \( c = \infty \) and \( L = 0 \) or \( \infty \).

**Lemma 5.1.** There is a Lévy process for which 0 is regular for \((0, \infty)\) and with
\[
\frac{X_t}{t} \xrightarrow{p} 0, \quad \text{as } t \downarrow 0, \quad \text{but with } \frac{X_t}{t} \xrightarrow{p} -1, \quad \text{as } t \downarrow 0. \tag{5.6}
\]
There is also a Lévy process with
\[
\frac{X_t}{t} \xrightarrow{p} \infty, \quad \text{as } t \to L, \quad \text{but with } \frac{X_t}{t} \xrightarrow{p} -\infty, \quad \text{as } t \to L, \tag{5.7}
\]
for \( L = 0 \) or \( L = \infty \).

**Proof of Lemma 5.1.** This is given in the Appendix.

Proof of Theorem 2.2. By a simple pathwise argument using (5.3), it easily follows that for \( L = \infty \) or \( L = 0 \), and \( c \in [0, \infty] \), we have \( \lim_{t \to L} \frac{\tau_u}{u} = \frac{1}{c} \) a.s. if and only if
\[
\lim_{t \to L} \frac{X_t}{t} = c \quad \text{a.s.} \tag{5.8}
\]

(a)(i) If \( E|X_1| < \infty \) and \( c = EX_1 \geq 0 \) then (5.8) with \( L = \infty \) holds by the strong law. Conversely, by Theorem 15 of [14], (5.8) implies that at least one of \( EX_1^+ \) or \( EX_1^- \) is finite or else \( X_t \to -\infty \). Since \( \limsup_{t \to \infty} X_t = \infty \), the latter possibility is ruled out and so is the possibility that \( EX_1^- = \infty \). Since \( c \in [0, \infty) \), the strong law and (5.8) then force \( E|X_1| < \infty \) and \( c = EX_1 \geq 0 \).

(a)(ii) If \( X \) is of bounded variation with \( d_X \geq 0 \) then \( X_t / t \to d_X \) a.s. as \( t \downarrow 0 \) by Theorem 39 of [14]. Hence (5.8) holds with \( c = d_X \). Conversely, by the same result, (5.8) implies \( X \) is of bounded variation and necessarily \( d_X \geq 0 \) since 0 is regular for \((0, \infty)\). It then follows that \( c = d_X \geq 0 \).

(b)(i) When \( 0 < EX_1 \leq E|X_1| < \infty \), we have \( EL_1^{-1} < \infty \) (e.g., Theorem 1 of [18]). Thus letting \( t \to \infty \) in
\[
\frac{X_{t^{1-\delta}}}{L_t} = \frac{H_t}{L_t} = \left( \frac{H_t}{t} \right) \left( \frac{t}{L_t^{\alpha}} \right), \tag{5.9}
\]
and using the strong law, we obtain \( H_t/t \to EX_1EL_1^{-1} \) as \( t \to \infty \). This implies \( EH_1 < \infty \) and \( EX_1 = EH_1/EL_1^{-1} \). Conversely, \( EH_1 < \infty \) implies \( 0 \leq EX_1 \leq E|X_1| < \infty \) by Theorem 8 of [17], and \( EL_1^{-1} < \infty \) implies \( X \) drifts to \( +\infty \) a.s. by Theorem 1 of [18], so in fact \( 0 < EX_1 \leq E|X_1| < \infty \).

(b)(ii) When \( X \) is of bounded variation, then \( \sigma^2 = 0 \), and by taking limits as \( t \downarrow 0 \) in (5.9), we obtain
\[
d_{L^{-1}}dX = dH. \tag{5.10}
\]

When \( dX > 0 \), \( X_t/t \to dX > 0 \) and \( \tau_u/u \to 1/dX < \infty \) (by (a)(ii)). Thus
\[
\frac{X_{\tau_u}}{u} = \frac{X_{\tau_u}}{\tau_u} \frac{\tau_u}{u} \to 1 \text{ a.s. as } u \downarrow 0.
\]
This implies \( dH > 0 \) by Theorem 4 of [17]. Hence by (5.10) \( d_{L^{-1}} > 0 \) also, and so \( c = dX = dH/d_{L^{-1}} \).

Conversely assume \( dH > 0 \), \( d_{L^{-1}} > 0 \) and \( \sigma^2 = 0 \). We show \( \lim_{u \downarrow 0} \frac{\tau_u}{u} = \frac{d_{L^{-1}}}{dH} \) a.s. Let \( T_u := \inf\{t > 0 : H_t > u\} \), \( u > 0 \). Then \( \tau_u = L_{T_u}^{-1} \). Hence by (5.9)
\[
\frac{X_{\tau_u}}{u} = \left( \frac{H_{T_u}}{T_u} \right) \left( \frac{T_u}{L_{T_u}^{-1}} \right) \to \frac{dH}{d_{L^{-1}}}
\]
Since \( \lim_{u \to 0} X_{\tau_u}/u = 1 \) a.s. when \( dH > 0 \) by Theorem 4 of [17], the result follows. \( \square \)

**Proof of Theorem 2.3.** We begin by recalling that from Theorem 1 of [18], \( E\tau_u < \infty \) for some, hence all, \( u \geq 0 \), iff \( X \) drifts to \( +\infty \) a.s., iff \( EL_1^{-1} < \infty \).

Use identity (8) on p.174 of Bertoin (1996) to write
\[
E\tau_u = \lim_{\lambda \downarrow 0} \frac{\kappa(\lambda, 0)}{\lambda} V_H(u) = EL_1^{-1}V_H(u), \quad u > 0, \tag{5.11}
\]
where
\[
V_H(u) = \int_0^\infty P(H_t \leq u)dt
\]
is the renewal function associated with \( H \).

(a) (i) For \( u \to \infty \): by the elementary renewal theorem (Kyprianou [29], Cor 5.3 p.114; note that there is no non-lattice restriction on the support of \( \Pi_X \), and the case \( EH_1 = \infty \) is covered, e.g., by Gut [23] Theorem 4.1 p.51) we have
\[
\lim_{u \to \infty} \frac{V_H(u)}{u} = \frac{1}{EH_1} \in [0, \infty), \tag{5.12}
\]
so we see that \( \lim_{u \to \infty} E\tau_u/u = 1/c \) for some \( c \in [0, \infty) \) iff \( EH_1 < \infty \) and \( EL_1^{-1} < \infty \), and then \( c = EH_1/EL_1^{-1} \). Since \( EH_1 < \infty \) is equivalent to \( 0 < EX_1 \leq E|X_1| < \infty \) when \( X_t \to \infty \) by Theorem 8 of [17], we have only left to observe that by Wald’s equation for Lévy processes, [24], \( EH_1/EL_1^{-1} = EX_1 \).
(ii) For $u \downarrow 0$: assume that $EL_1^{-1} < \infty$ and $d_H > 0$. Since $\mathcal{H}_t \geq d_H t$, $t \geq 0$, it follows easily that

$$V_H(u) := \int_0^\infty P(\mathcal{H}_t \leq u) dt = \int_0^{u/d_H} P(\mathcal{H}_t \leq u) dt \leq e^{qu/d_H} \int_0^{u/d_H} e^{-qt} P(\mathcal{H}_t \leq u) dt = e^{qu/d_H} V_H(u),$$

while trivially $V_H(u) \leq V_H(u)$. Thus by Theorem III.5 of Bertoin [7], which applies to proper subordinators, we have

$$\lim_{u \downarrow 0} V_H(u) = 1,$$

and so $\lim_{u \rightarrow \infty} V_H(u) = 1/c$ implies by (5.11) that (5.13) holds with $d_H$ replaced by $cEL_1^{-1} > 0$. By Lemma 4, p.52 of [14], we have

$$V_H(u) \approx \frac{1}{d_H + \int_0^u \Pi_H(y) dy + uq}, \quad \text{for all } u > 0.$$  

(5.14)

Hence $d_H > 0$, since $d_H = 0$ would imply $\lim_{u \rightarrow \infty} V_H(u) = \infty$, a contradiction. \qed

(b) In case $c = 0$, we see from (5.11) and (5.12) that $\lim_{u \rightarrow \infty} E\tau_u/u = EL_1^{-1}/d_H$ by (5.11). Conversely, $\lim_{u \rightarrow \infty} E\tau_u/u = 1/c$ implies by (5.11) that (5.13) holds with $d_H$ replaced by $cEL_1^{-1} > 0$. By Lemma 4, p.52 of [14], we have

$$\lim_{u \rightarrow \infty} \frac{V_H(u)}{u} = \frac{1}{d_H + \int_0^u \Pi_H(y) dy + uq},$$

for all $u > 0$.  

(5.15)

Hence $d_H > 0$, since $d_H = 0$ would imply $\lim_{u \rightarrow \infty} V_H(u)/u = \infty$, a contradiction.

(c) For the case $c = \infty$, supposing $E\tau_u < \infty$ for each $u > 0$, (5.11) and (5.12) show that $\lim_{u \rightarrow \infty} E\tau_u/u = 0$ iff $EL_1^{-1} < \infty$ and $EH_1 = \infty$, while for $u \downarrow 0$, the case $c = \infty$ cannot arise; $\liminf_{u \rightarrow 0} E\tau_u/u > 0$ follows from (5.11) and (5.14). \qed

The following lemma, which is a Lévy process version of a result of [30] for random walk, is needed in the proofs of Theorems 2.4 and 2.5.

**Lemma 5.2. (Uniform Integrability of $\tau_u$.)** Suppose $X$ is a Lévy process with $0 < EX_1 \leq E|X_1| < \infty$ and $\tau_u = \inf\{t > 0 : X_t > u\}$, $u > 0$. Then $\tau_u/u$ are uniformly integrable as $u \rightarrow \infty$, i.e.,

$$\lim_{x \rightarrow \infty} \limsup_{u \rightarrow \infty} E\left(\frac{\tau_u}{u} 1_{\{\tau_u > x\}}\right) = 0.$$  

(5.15)

**Proof of Lemma 5.2.** The random walk result of [30] can be transferred using a stochastic bound due to Doney [13]. First consider the case when $\Pi \equiv 0$. Then $X_t = t\gamma + \sigma B_t$, where $\gamma = EX_1 > 0$, $\sigma \geq 0$, and $(B_t)_{t \geq 0}$ is a standard Brownian motion. In this case $\tau_u$ has an inverse Gaussian distribution and $E\tau_u^2 = u\sigma^2/\gamma^3$, which immediately implies uniform integrability of $\tau_u/u$. 

So, assume $\Pi$ is not identically 0. Then $\Pi(x_0) > 0$ for some $x_0 > 0$, and by rescaling if necessary we can assume $c_1 := \Pi(1) > 0$. As in [18], let $\sigma_0 = 0$ and let $\sigma_n$, $n = 1, 2, \ldots$, be the successive times at which $X$ takes a jump of absolute value greater than 1. Then $\epsilon_i := \sigma_i - \sigma_{i-1}$ are i.i.d exponential rvs with $E(\epsilon_1) = 1/c_1$. Define $S_n := X_{\sigma_n}$, $n = 1, 2, \ldots$, and $\tau^S_u = \min\{n \geq 1 : S_n > u\}, u > 0$. Then $S_n$ is a random walk with step distribution $Y_i := X_{\sigma_i} - X_{\sigma_{i-1}} \overset{D}{=} X_{\epsilon_i}$. By Wald’s equation, $EY_1 = EX_1/c_1 > 0$. Thus by [30], $\tau^S_u/u$ are uniformly integrable.

Now we can use similar calculations as on p.287 of [18] to bound the expression on the left of (5.15) in terms of a similar expression involving $\tau^S_u$. For any $Z \geq 0$ and any $a > 0$

$$E(Z; Z > a) = \int_{z>a} P(Z > z)dz + aP(Z > a).$$

(5.16)

Taking $u > 0$, $x > 0$, $c > 1/c_1$, we obtain

$$E \left( \frac{\tau_u}{uc} 1_{\{ \frac{\tau_u}{uc} > x \} } \right) = u^{-1} \int_{y>xu} P(\tau_u > yc) dy + xP(\tau_u > xuc).$$

(5.17)

By Theorem 2.1 we have $\tau_u/u \overset{P}{\rightarrow} 1/EX_1$ as $u \rightarrow \infty$. So the second term on the righthand side of (5.17) tends to 0 as $u \rightarrow \infty$ once $xc > 1/EX_1$. As on p.287 of [18] we have

$$P(\sigma_j \leq \tau_u < \sigma_{j+1}) = P(\tilde{m}_0 \leq u, \tau^S_u-\tilde{m}_0 = j), j \geq 1,$$

where $\tilde{m}_0$ is a finite rv independent of $(S_n)_{n=1,2,\ldots}$. The first term on the righthand side of (5.17) is bounded by

$$u^{-1} \sum_{n \geq \lfloor xu \rfloor} P(\tau_u > nc),$$

(5.18)

and now we argue as follows:

$$u^{-1} \sum_{n \geq \lfloor xu \rfloor} P(\tau_u > nc) \leq u^{-1} \sum_{n \geq \lfloor xu \rfloor} P(\tau_u \geq \sigma_n) + u^{-1} \sum_{n \geq \lfloor xu \rfloor} P(\sigma_n > nc)$$

$$= u^{-1} \sum_{j \geq \lfloor xu \rfloor} (j - \lfloor xu \rfloor + 1)P(\sigma_j \leq \tau_u < \sigma_{j+1})$$

$$+ u^{-1} \sum_{n \geq 1} P \left( \sum_{i=1}^{n} \epsilon_i > nc \right).$$

(5.19)

Since $\epsilon_i$ are i.i.d. with a finite exponential moment and $E\epsilon_i = 1/c_1 < c$, the sum in the second term on the righthand side of (5.19) is convergent, and hence this term is $o(1)$ as $u \rightarrow \infty$. The first term on the
righthand side of (5.19) is

\[ u^{-1} \sum_{j \geq \lfloor xu \rfloor} (j - \lfloor xu \rfloor + 1) P(\tilde{m}_0 \leq u, \tilde{\tau}_u - \tilde{m}_0 = j) = u^{-1} \sum_{j \geq \lfloor xu \rfloor} (j - \lfloor xu \rfloor + 1) \int_0^u P(\tau^S_u \geq y) \, dy \]

\[ \leq u^{-1} \sum_{n \geq \lfloor xu \rfloor} \int_0^u P(\tau^S_u \geq n) \, dy \]

\[ \leq u^{-1} \int_{y > \lfloor xu \rfloor - 1} P(\tau^S_u > y) \, dy \]

\[ \leq E \left( \frac{\tau^S_u}{u} \mathbf{1}_{\tau^S_u > \frac{y}{u}} \right), \]

if \( xu \geq 4 \), where the last inequality comes from (5.16). Since \( \tau_u^S / u \) are uniformly integrable by Lai’s result we get (5.15).

\[ \square \]

**Remark 5.1.** Lemma 5.2 could be used to give an alternative proof of Part (a)(i) of Theorem 2.3 from Theorem 2.2. This approach however would not work for Part (a)(ii) of Theorem 2.3, since \( \tau_u / u \) are not uniformly integrable as \( u \downarrow 0 \). This is because the almost sure limit in Theorem 2.2 does not agree with the limit in mean in Theorem 2.3 as \( u \downarrow 0 \).

**Proof of Theorem 2.4.** (a) We first observe that (2.14) is equivalent to

\[ \lim_{x \rightarrow 1/L} \frac{\kappa(0, x) - \kappa(0, 0)}{\kappa(\xi x, x)} = \frac{c}{c + \xi}, \text{ for each } \xi > 0. \quad (5.20) \]

When \( L = \infty \) this because \( \kappa(0, 0) = q = 0 \) and our assumption that \( \limsup_{t \rightarrow \infty} X_t = \infty \). When \( L = 0 \) we have, by (1.3), that \( \kappa(\xi x, x) \rightarrow \infty \) as \( x \rightarrow 1/L \) for each \( \xi > 0 \) unless \( d_H = d_{L-1} = 0 \) and \( \Pi_{L-1,H} \) is a finite measure. But this is impossible since 0 is regular for \( (0, \infty) \), so (5.20) is equivalent when \( L = 0 \) also.

From (1.4) we have, for \( u > 0, \nu > 0 \),

\[ \mu \int_{u \geq 0} e^{-\mu u} E \left( e^{-\nu G_{\tau_u}; \tau_u < \infty} \right) du = \frac{\kappa(0, \mu) - \kappa(0, 0)}{\kappa(\nu, \mu)}. \]

Take \( y > 0 \) and replace \( \mu \) by \( \mu / y \), \( u \) by \( uy \), and \( \nu \) by \( \nu / y \) in this to get

\[ \mu \int_{u \geq 0} e^{-\mu u} E \left( e^{-\nu G_{\tau_u}; \tau_u < \infty} \right) du = \frac{\kappa(0, \mu / y) - \kappa(0, 0)}{\kappa(\nu / y, \mu / y)}. \quad (5.21) \]
(2.13) implies \( G_{\tau_{u,-}}/y \xrightarrow{p} u/c \), as \( y \to L \), for each \( u > 0 \). So the lefthand side of (5.21) tends to \( c/(c+\nu/\mu) \) as \( y \to L \), and then (2.14) follows from (5.20) and the righthand side of (5.21). The proof that (2.14) implies (2.13) is analogous to that in Theorem 2.1.

(b) By the strong law when \( L = \infty \) and by Theorem 39 of [14] when \( L = 0 \), it suffices to prove that for \( c \in [0, \infty) \)

\[
\lim_{t \to L} \frac{X_t}{t} = c \quad \text{a.s.,} \tag{5.22}
\]

if and only if

\[
\lim_{u \to L} \frac{G_{\tau_{u,-}}}{u} = \frac{1}{c} \quad \text{a.s.} \tag{5.23}
\]

A simple pathwise argument shows that (5.22) implies (5.23) when \( c > 0 \), but the case \( c = 0 \) is a little trickier. Since the following argument works whenever \( c \in [0, \infty) \), we prove it under that assumption. So assume that (5.22) holds with \( c \in [0, \infty) \). Then \( X_t/t \to c \) as \( t \to L \). If (5.23) fails, then

\[
\liminf_{u \to L} \frac{G_{\tau_{u,-}}}{u} < \frac{1}{c},
\]

since under (5.22), \( \frac{G_{\tau_{u,-}}}{u} \leq \frac{\tau_u}{u} \to \frac{1}{c} \) as \( u \to L \), by Theorem 2.2. Now consider the random level \( Z_u = X_{\tau_{u,-}} \), and observe that

\[
\tau_{Z_u} = \tau_u, \quad X_{G_{\tau_{u,-}}} = X_{\tau_{u,-}} = Z_u.
\]

Writing

\[
\frac{X_{G_{\tau_{u,-}}}}{G_{\tau_{u,-}}} = \frac{Z_u - u}{u} \frac{1}{G_{\tau_{u,-}}},
\]

it then follows that

\[
\liminf_{u \to L} \frac{Z_u}{u} < 1.
\]

Thus

\[
\limsup_{u \to L} \frac{X_{\tau_u}}{Z_u} = \limsup_{u \to L} \frac{X_{\tau_u}}{Z_u} \geq \limsup_{u \to L} \frac{u}{Z_u} > 1.
\]

In particular it is not the case that \( \lim_{v \to L} \frac{X_{\tau_u}}{v} = 1 \) a.s. This implies \( E|X| = \infty \) when \( L = \infty \), by Theorem 8 of [17], and \( X \) is not of bounded variation when \( L = 0 \), by Theorem 4 of [17]. In either case (5.22) fails to hold which is a contradiction.

Conversely assume (5.23) holds for some \( c \in [0, \infty) \). Then for any \( a > c \), \( G_{\tau_{u,-}} > ua^{-1} \) eventually. Hence \( X_{ua^{-1}} \leq u \) eventually. This implies

\[
\limsup_{t \to L} \frac{X_t}{t} \leq c.
\]
If $L = \infty$, then arguing as in the proof of Theorem 2.2 (a)(i), (5.24) implies that $0 \leq EX_1 \leq E|X_1| < \infty$ and so (5.22) holds with $c = EX_1 \geq 0$. Since (5.22) implies (5.23), the constant $c$ for which (5.23) was assumed to hold must also have been $c = EX_1$, completing the proof of (i). If $L = 0$ then (5.24) forces $X$ to have bounded variation with $dX \geq 0$ since 0 is regular for $(0, \infty)$. In that case (5.22) holds with $c = dX$, and so again since (5.22) implies (5.23), the constant $c$ for which (5.23) was assumed to hold must also have been $c = dX$, completing the proof of (ii).

(c) Finally, suppose $0 < EX_1 \leq E|X_1| < \infty$. Then (5.23) holds with $c = EX_1$ and, further, $G_{\tau_u}/u$ are uniformly integrable as $u \to \infty$ by Lemma 5.2. Thus we get $\lim_{u \to \infty} E(G_{\tau_u}/u) = 1/EX_1$. \hfill \Box

**Proof of Theorem 2.5.** Since $0 < EX_1 \leq E|X_1| < \infty$, we have by Theorems 2.2 and 2.4

$$\lim_{u \to \infty} \frac{G_{\tau_u}}{u} = \lim_{u \to \infty} \frac{\tau_u}{u} = \frac{1}{EX_1} \text{ a.s.}$$

The assumptions on $X$ imply that $H$ does not have a lattice jump distribution, and hence it follows from [10] that

$$X_{\tau_u} - u \overset{D}{\to} Y, \text{ as } u \to \infty,$$

where $Y$ is the rv defined in the statement of Theorem 2.5. Since $\tau_u/u$, and consequently $G_{\tau_u}/u$ also, are uniformly integrable as $u \to \infty$, by Lemma 5.2, the result follows. \hfill \Box

### 6. Proofs for Section 3

We assume throughout this section the setup of Section 3. Let $\mathcal{F}_{\tau_u}$ be the $\sigma$-algebra generated by $X$ up to time $\tau_u$. By Corollary 3.11 of [29], for any $Z_u$ which is nonnegative and measurable with respect to $\mathcal{F}_{\tau_u}$, we have

$$E(Z_u; \tau_u < \infty) = E^\ast(Z_u e^{-\nu_0 X_{\tau_u}}).$$

This immediately yields the following lemma, which can be found in Theorem IV.7.1 of [4] for compound Poisson processes with negative drift. Our proof is analogous to that in [4].

**Lemma 6.1.** Suppose $\mu^\ast < \infty$ and $Y_u$ are $\mathcal{F}_{\tau_u}$-measurable rvs such that $Y_u \overset{P}{\to} 0$ as $u \to \infty$. Then $Y_u \overset{P(u)}{\to} 0$.

**Proof of Lemma 6.1:** For $\varepsilon > 0$, by (6.1),

$$P(u)(|Y_u| > \varepsilon) = \frac{P(|Y_u| > \varepsilon, \tau_u < \infty)}{P(\tau_u < \infty)} = \frac{E^\ast(e^{-\nu_0(X_{\tau_u}-u)}; |Y_u| > \varepsilon)}{e^{\nu_0 u} P(\tau_u < \infty)}.$$
Stability of the Exit Time

Since $\mu^* < \infty$ we have by (3.5) that the denominator here is bounded away from 0, hence the result. □

**Proof of Theorem 3.1** Since $X$ is a Lévy process under $P^*$ with $E^*X_1 = \mu^* \in (0, \infty)$, it follows easily from the strong law that

$$
\frac{X_{\tau_u}}{u} \to 1, \quad \frac{G_{\tau_u}}{u} \to \frac{1}{\mu^*} \quad \text{and} \quad \frac{\tau_u}{u} \to \frac{1}{\mu^*}, \quad P^* \text{-a.s., as } u \to \infty. \tag{6.2}
$$

(3.6) is then immediate from Corollary 6.1.

For (3.7), use Theorem 2.5, (3.5) and (6.1) to deduce that, as $u \to \infty$,

$$
E^* \left( \frac{X_{\tau_u}}{u} e^{-\nu_0 O_u} \mathbf{1}_{\{X_{\tau_u} > u\}} \right) \sim \frac{C}{u}. \tag{6.3}
$$

The limit involving $G_{\tau_u}$ is similar. For the final limit in (3.7), first observe that

$$
E^* \left( \frac{X_{\tau_u}}{u} e^{-\nu_0 O_u} \mathbf{1}_{\{X_{\tau_u} > u\}} \right) \sim \frac{C}{u}. \tag{6.3}
$$

Now let $O_u := X_{\tau_u} - u, \ u > 0$. Then $(X_{\tau_u}/u) e^{-\nu_0 O_u}$ is uniformly integrable, because for $x > 1$ and $c_0 := \sup_{y \geq 0} (ye^{-\nu_0 y}) = (e\nu_0)^{-1}$ we have

$$
E^* \left( \frac{X_{\tau_u}}{u} e^{-\nu_0 O_u} \mathbf{1}_{\{X_{\tau_u} > x\}} \right) \leq \frac{c_0}{u} + e^{-\nu_0 (x-1)u}.
$$

Letting $u \to \infty$ then $x \to \infty$ shows the uniform integrability. Since $X_{\tau_u} - u \overset{D^*}{\to} Y$ and $X_{\tau_u}/u \overset{P^*}{\to} 1$ by (6.2), we have

$$
E^* \left( \frac{X_{\tau_u}}{u} e^{-\nu_0 O_u} \right) \sim C^{-1} E^* \left( \frac{X_{\tau_u}}{u} e^{-\nu_0 O_u} \right) \to C^{-1} e^{-\nu_0 Y} = 1,
$$

completing the proof. □

**APPENDIX**

**Proof of Lemma 5.1.** We first construct a Lévy process satisfying (5.6). For the characteristics of $X$ we take $\gamma = -2, \sigma = 0$ and the Lévy measure given by

$$
\Pi^+_X(x) = \frac{1}{x|\ln x|}, \quad \Pi^-_X(x) = \Pi^+_X(x) + \frac{\ln 2}{x|\ln x|^2}, \quad 0 < x < 1/2
$$

$$
\Pi^+_X(x) = \Pi^-_X(x) = 0, \quad x \geq 1/2.
$$
Then $X$ is not of bounded variation since
\[ \int (|x| \wedge 1) \Pi(dx) = \infty, \]
and consequently 0 is regular for $(0, \infty)$. Further one can easily check that (2.8) holds with $c = -1$, and so
\[ \frac{X_t}{t} \xrightarrow{p} -1 \text{ as } t \downarrow 0 \]
by Theorem 2.1 of [16]. Also, the argument given in Theorem 2.1 that (2.6) implies (2.5) when $L = 0$, shows that under (2.8),
\[ P(\sup_{0 \leq s \leq t} |X_s + s| > \varepsilon t) \to 0 \text{ as } t \downarrow 0. \]
From this we conclude that
\[ \frac{X_t}{t} \xrightarrow{p} 0 \text{ as } t \downarrow 0, \]
completing the example.

We now construct a Lévy process satisfying (5.7). This is based on Example 3.5 in [27], which constructs a random walk $S_n = \sum_{i=1}^n Y_i$ with i.i.d. summands $Y_i$ which satisfying
\[ \frac{S_n}{n} \xrightarrow{p} -\infty \quad \text{and} \quad \frac{\overline{S}_n}{n} = \frac{\max_{1 \leq j \leq n} S_j}{n} \xrightarrow{p} \infty. \quad (6.4) \]
This is done by finding a random walk which is negatively relatively stable (NRS) as $n \to \infty$, i.e., with
\[ \frac{S_n}{D(n)} \xrightarrow{p} -1, \quad (n \to \infty), \quad (6.5) \]
for a norming sequence $D(n) > 0$ with $D(n)/n \to \infty$ satisfying
\[ \lim_{n \to \infty} \sum_{j = \ell(n)}^n P(S_1 > xD(j)) = \infty, \quad (6.6) \]
where $\ell(n)$ is inverse to $D(n)$. The sequences $D(n)$ and $\ell(n)$ are strictly increasing to $\infty$ as $n \to \infty$ and satisfy $D(n) = -nA(D(n))$ (where $A(\cdot)$ is defined in (2.2)) and $\ell(n) = -n/A(n)$. The function $-A(x)$ is positive for $x$ large enough, slowly varying as $x \to \infty$, and tends to $\infty$ as $x \to \infty$.

(i) Consider first the case $L = \infty$. Let $(N_t)_{t \geq 0}$ be a Poisson process of rate 1 independent of the $Y_i$ and set $X_t := S_{N_t}$, $t \geq 0$, where $S_n$ is as in (6.4). Then the compound Poisson process $X_t$ satisfies (5.7) with $L = \infty$. This is fairly straightforward to check and we omit the details.

(ii) Now consider the case $L = 0$. For this we have to modify Example 3.5 in [27] to work as $t \downarrow 0$. Details are as follows.
We construct a Lévy process $X_t$ which is NRS as $t \downarrow 0$, i.e., is such that
\[ \frac{X_t}{b(t)} \overset{p}{\rightarrow} -1 \text{ as } t \downarrow 0, \] (6.7)
for a nonstochastic function $b(t) > 0$, with $b(t) \downarrow 0$ and $b(t)/t \to \infty$ as $t \downarrow 0$. To do this, it will be useful to summarize here some properties concerning (negative) relative stability at 0 of $X_t$; for reference, see [16] (and replace $X$ by $-X$). We assume that $\Pi_X(x) > 0$ for all $x > 0$. We then have that $X_t \in \text{NRS}$ if and only if $\sigma = 0$ and the function $A(x)$ defined in (2.2) is strictly negative for all $x$ small enough, $x \leq x_0$, say, and satisfies
\[ \lim_{x \downarrow 0} \frac{A(x)}{x} = -\infty. \] (6.8)
When $A(x) < 0$ for $x \leq x_0$, there is an $x_1 \leq x_0$ so that the function
\[ D(x) := \sup \left\{ y \geq x_0 : \frac{-A(y)}{y} \geq \frac{1}{x} \right\}, \quad 0 < x \leq x_1, \] (6.9)
is strictly positive and finite and satisfies
\[ D(x) = -xA(D(x)) \]
for all $x \leq x_1$. It is easily seen to be strictly increasing on $x \leq x_1$ (by the continuity of $y \mapsto -A(y)/y$ with $D(0) = 0$. Thus for small enough $y$ we can define the inverse function
\[ \ell(y) = \sup \{ x : D(x) \leq y \} = \inf \{ x : D(x) > y \}. \]
When (6.8) holds, $-A(x)$ is slowly varying as $x \downarrow 0$, and as a consequence $D(x)$ and $\ell(x)$ are both regularly varying with index 1 as $x \downarrow 0$ (see Bingham, Goldie and Teugels, [11], Theorem 1.5.12). Also, when (6.8) holds, it is easy to check that $-A(y)/y$ is strictly decreasing for $y$ small enough, so $\ell(y)$ is continuous and strictly increasing, with $\ell(0) = 0$, and
\[ \ell(y) = \frac{y}{-A(y)}, \]
for $y$ small enough. Finally, we can take $b(t) = D(t)$ in (6.7) to get negative relative stability of $X$ in the form:
\[ \frac{X_t}{D(t)} \overset{p}{\rightarrow} -1 \text{ as } t \downarrow 0. \] (6.10)
To construct the process required in the lemma, we will specify a Lévy measure $\Pi_X$ for $X$ such that
\[ \frac{D(t)}{t} \to \infty, \text{ as } t \downarrow 0, \] (6.11)
consequently \( t(t)/t \to 0 \), and

\[
\int_{t(t)}^{t} \prod_{X}^{+} (x D(s)) \, ds \to \infty, \quad \text{as } t \downarrow 0,
\]

(6.12)

for all \( x > 0 \). (6.10) then implies \( X_{t}/t \xrightarrow{P} -\infty \) as \( t \downarrow 0 \). We claim that in addition (6.10)--(6.12) imply

\[
\frac{X_{t}}{t} \xrightarrow{P} \infty \quad \text{as } t \downarrow 0.
\]

(6.13)

To prove (6.13) from (6.10)--(6.12), fix \( t > 0 \). (6.10) then implies

\[
P(\overline{X}_{t} > xt) = \lim_{t \to \infty} P \left( \max_{1 \leq j \leq n} X(j/n) > x D(\ell(t)) \right)
\]

\[
\geq \liminf_{n \to \infty} \sum_{nt(t) \leq j \leq nt} \left[ P \left( \max_{k=1} \frac{\Delta(k/n)}{D(k/n)} \leq 2x < \frac{\Delta(j/n)}{D(j/n)} \right) \right],
\]

(6.14)

where

\[
\Delta(k/n) := X(k/n) - X((k-1)/n), \quad k = 1, 2, \ldots,
\]

are i.i.d. with distribution the same as that of \( X(1/n) \). Given \( \varepsilon \in (0,1) \), by (6.10) there is a \( t_0 > 0 \) such that \( P(X((j-1)/n) > -x D(j/n)) > 1 - \varepsilon \) when \( j/n \leq t \leq t_0 \). Thus, keeping \( t \leq t_0 \),

\[
P(\overline{X}_{t} > xt) \geq (1 - \varepsilon) \liminf_{n \to \infty} \sum_{nt(t) \leq j \leq nt} P \left( \max_{j+1 \leq k \leq nt} \frac{\Delta(k/n)}{D(k/n)} \leq 2x < \frac{\Delta(j/n)}{D(j/n)} \right).
\]

Here the sum equals

\[
P(\Delta(j/n) > 2x D(j/n)), \quad \text{for some } j \in [nt(t), nt] \right) = 1 - \prod_{nt(t) \leq j \leq nt} P(X(1/n) \leq 2x D(j/n))
\]

\[
\geq 1 - \exp \left( - \sum_{nt(t) \leq j \leq nt} P(X(1/n) > 2x D(j/n)) \right).
\]

Noting that

\[
n \int_{t(t)}^{t+1/n} P(X(1/n) > 2x D(s)) \, ds \leq n \sum_{nt(t) \leq j \leq nt} \int_{j/n}^{(j+1)/n} P(X(1/n) > 2x D(s)) \, ds
\]

\[
\leq \sum_{nt(t) \leq j \leq nt} P(X(1/n) > 2x D(j/n)) \, ds,
\]

and employing the fact that \( \lim_{n \to \infty} n P(X(1/n) > a) = \prod_{X}^{+} (a) \) for all \( a > 0 \) (cf. [7] p.39) we get

\[
P(\overline{X}_{t} > xt) \geq (1 - \varepsilon) \liminf_{n \to \infty} \left[ 1 - \exp \left( - \int_{t(t)}^{t+1/n} P(X(1/n) > 2x D(s)) \, ds \right) \right]
\]

\[
= (1 - \varepsilon) \left( 1 - \exp \left( - \int_{t(t)}^{t} \prod_{X}^{+} (2x D(s)) \, ds \right) \right).
\]
Stability of the Exit Time

The last expression tends to 1 as \( t \downarrow 0 \) then \( \varepsilon \downarrow 0 \), provided (6.12) holds. Thus (6.13) will follow from (6.10)–(6.12), as claimed.

It remains to give an example where (6.10)–(6.12) hold. Define

\[ L(x) = e^{(-\log x)^{\beta}}, \quad 0 < x < e^{-1}, \]

and keep \( \frac{1}{2} < \beta < 1 \). Choose a Lévy measure \( \Pi_X \) which satisfies

\[ \Pi_X^+(x) = -2L'(x) = \frac{2\beta(-\log x)^{\beta-1}L(x)}{x} \]

and

\[ \Pi_X^-(x) = -L'(x) = \Pi_X^+(x)/2, \]

for \( x \) small enough, \( x \leq x_0 \), say. (Note that \( \Pi_X^+(x) \) and \( \Pi_X^-(x) \) are infinite at 0 and decrease to 0 as \( x \to \infty \).) A straightforward calculation using (2.2), gives, for \( x > 0 \),

\[ A(x) = \gamma + \Pi_X^+(1) - \Pi_X^-(1) + 1 - L(x). \]

Thus \( A(x) \to -\infty \) as \( x \downarrow 0 \), and

\[ \frac{-A(x)}{x\Pi_X(x)} \sim \frac{L(x)}{-3L'(x)} \sim \frac{(-\log x)^{1-\beta}}{3\beta} \to \infty \quad \text{as} \quad x \downarrow 0. \]  

(6.15)

Thus by (6.8), \( X \) is negatively relatively stable at 0 and (6.10) holds with \( D(t) \) as in (6.9). We have \( D(t) = -tA(D(t)) \) and \( \ell(t) = -t/A(t) \) for small enough \( t > 0 \). Since \( -A(x) \to \infty \) as \( x \downarrow 0 \), (6.11) also holds. Now \( L(x) \) is slowly varying as \( x \downarrow 0 \), so \( \Pi_X^+(x) \) is regularly varying with index \( -1 \) as \( x \downarrow 0 \). It therefore suffices to check (6.12) with \( x = 1 \). Note also that \( \log(D(t)) \sim \log t \) as \( t \downarrow 0 \), because \( A(\cdot) \) is slowly varying at 0. Hence for some constant \( c_2 > 0 \), as \( t \downarrow 0 \),

\[ \int_{\ell(t)}^{t} \frac{\Pi_X^+(D(s))ds}{s} = \int_{\ell(t)}^{t} \frac{D(s)\Pi_X^+(D(s))}{-sA(D(s))}ds \]

\[ \sim 3\beta \int_{\ell(t)}^{t} \frac{(-\log D(s)^{\beta-1}}{s}ds \]

\[ \geq 3\beta(-\log t)^{\beta-1}(\log t - \log \ell(t)) \]

\[ \geq c_2(-\log t)^{2\beta-1} \to \infty \]

(because \( \beta > \frac{1}{2} \)). Thus (6.12) holds too. \( \square \)
